Law of Refraction in Optical Fiber Communication

Overview

Snell's law of refraction describes how light bends when passing from one medium to another with a different refractive index. Optical fibers are thin glass rods that use the properties of light reflection and refraction to transmit data over long distances. Refraction and total internal reflection (TIR) are the two fundamental optical principles that allow light to propagate through optical fibers over long distances with minimal loss. Understanding these mechanisms is essential for designing, installing, and troubleshooting fiber networks in FTTH. Since each mode travels at a different velocity on the fiber, an optical bit launched into the
